

A LIVING TRADITION, SHARED

Souls of Muse

We use AI to help people pass the art of playing musical instruments on to one another.

A community, a service and a family of creative tools built around human musical mentorship.

Watch the film · 2:56 ↗ | Explore the developments ↗

08	**Music and filmmaking with Muse**	Completed local masters

How to read this dossier

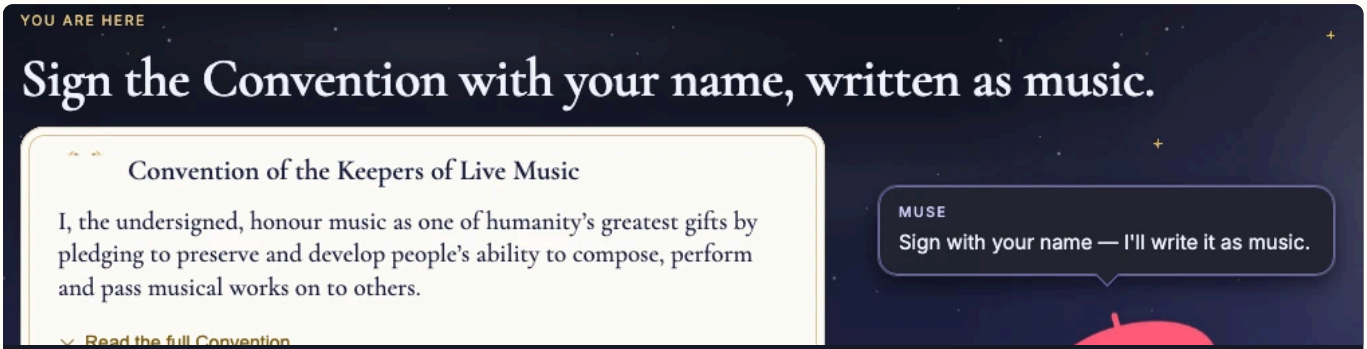

Each development separates what was built, the latest result, the evidence available and the remaining work. A local application, a public pilot, an experiment and a finished film are different kinds of result.

Cloud pilot

Souls of Muse & Muse Lesson

A service for human musical mentorship

Musicians need a shared place to meet, practise and pass on skills. Muse Lesson helps a human teacher guide another musician across a language barrier. The teacher leads; Muse supports the exchange.

Current public entrance. The community interface and the capability report describe different parts of the service.

WHAT WE BUILT

The hackathon work brought the community portal, lesson interface and our own Harness together: participant login, roles, text sessions, English–Vietnamese interpretation, speech recognition, approval before delivery and spoken replies.

HOW IT WORKS

The Harness manages model roles, musical terminology, session state and delivery rules. Speech becomes a draft interpretation; a person can review and approve it before the other participant hears it. Muse is a model dependency inside this orchestration.

MODELS & TOOLS Meta speech recognition · Muse Spark · MMS-TTS for English and Vietnamese

LATEST RESULT · 5 NOVEMBER

The current portal and lesson code were merged and published on 5 November. A live check confirms that sessions, login, approval, speech recognition and TTS are enabled. The public service identifies itself as a pilot.

EVIDENCE AVAILABLE

The public portal, code repository and capability endpoint are available. The portal includes the Convention, Leagues and lesson demonstration screens.

Current boundary

Full human acceptance of a bilingual lesson and the target response time remain open. Live media rooms, automatic matching and the watch application are not enabled in this cloud pilot.

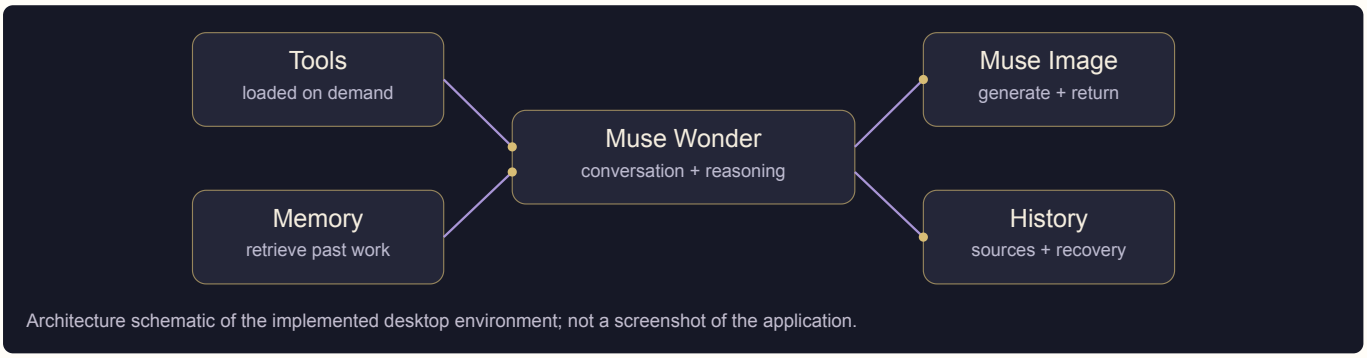

Open the service ↗ Inspect source ↗ Capability report ↗

Installed local application

MetaMezonin

A desktop environment built around Muse

A creative assistant needs tools, working memory and a place to keep its work. MetaMezonin provides that environment around Muse Wonder on the desktop.

Architecture schematic of the implemented desktop environment; not a screenshot of the application.

WHAT WE BUILT

The event work established an installed application with tools loaded on demand, persistent memory and retrieval, source-linked history, and a Muse Image route that can return generated imagery to Wonder for further work.

HOW IT WORKS

A custom runtime connects a conversation to tool discovery, execution and memory. Image generation is part of the same working context. Recovery scenarios and both source-level and packaged-application checks were recorded.

MODELS & TOOLS Muse Wonder via Meta Model API · Muse Image

LATEST RESULT · 5 NOVEMBER

The installed build and its recovery behavior are documented. A Muse assistant in MetaMezonin also contributed an earlier screenplay revision and substantive review to Ganesha.

EVIDENCE AVAILABLE

Installed build, source checks, packaged checks and recovery records are retained with the project. The Ganesha case provides a concrete example of work produced through this environment.

Current boundary

This is a separate desktop product from TopDog Colors. Proposed 3D avatars, movement analysis and home-practice extensions are future work. A public installer is not linked in this dossier.

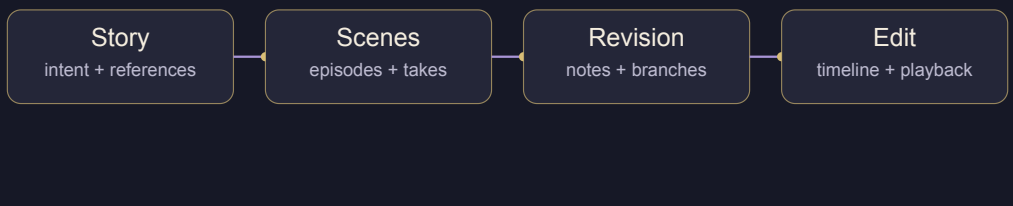

See the production case ↗

Working local studio · active development

TopDog Colors

A media studio for musicians

Musicians need to turn a story and a collection of shots into a music video. TopDog Colors gives that work an editable visual workspace.

Studio workflow schematic. The stages describe editable work, not an unattended end-to-end generation claim.

WHAT WE BUILT

Building on the pre-existing studio, the hackathon work restored the Muse subscription route and developed a new editing interface: episode navigation, a player and timeline, three working slots, edit notes, change branches and a visual reference library.

HOW IT WORKS

The interface connects scenes, references and revisions. The current library was checked with 82 distinct images and six branches. Playback, timeline controls, closing behavior, navigation and a compact window layout were exercised.

MODELS & TOOLS Muse Wonder Full through the subscription workflow; current interface implementation used OpenAI Codex

LATEST RESULT · 5 NOVEMBER

The current interface passed 38 project checks and a TypeScript check. The filmed demonstration uses the real studio window. A separate restored-studio run records actual Wonder Full work.

EVIDENCE AVAILABLE

Source, application builds, scene manifests and checks exist locally. The included live-action film shows the studio in use as the story returns to the day's events.

Current boundary

Agent execution is disabled in the current interface-editing build. The spoken question in the live-action film is a staged macOS voice playback. The historical studio itself predates the event; restoration and the specific new work are the event contribution.

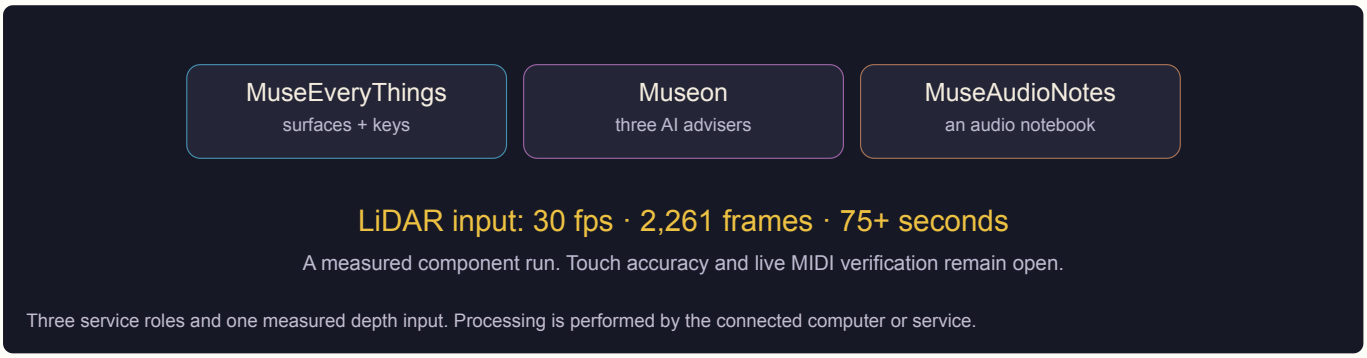

Watch the live-action film ↗

Local prototypes · demonstrated components

Three services for Ray-Ban Meta

Seeing, listening and supporting musicians

Glasses can bring assistance into the musician's field of view and ear, while a connected computer or service performs the processing.

Three service roles and one measured depth input. Processing is performed by the connected computer or service.

WHAT WE BUILT

Three named services share a visual and voice-oriented interface: MuseEveryThings for musical surfaces and keys; Museon for a three-adviser contract review; MuseAudioNotes for an audio notebook. A separate depth receiver adds physical touch and hover sensing.

HOW IT WORKS

MuseEveryThings uses SAM 3.1 and DINOv2 in the vision work. Museon combines document reading with a council of Wonder and Spark advisers. MuseAudioNotes uses Spark to read chord material. The LiDAR branch receives depth from an iPhone over USB and calibrates the support plane.

MODELS & TOOLS SAM 3.1 · DINOv2 · Muse Wonder · Muse Spark

LATEST RESULT · 5 NOVEMBER

Museon was reported complete on its demo contract, finding all 18 planted issues. The other two services are in advanced prototype development. The overnight LiDAR run delivered 2,261 frames at 30 fps for more than 75 seconds with no disconnects.

EVIDENCE AVAILABLE

Local service code, a clickable hub and recorded depth outputs exist. The live depth run produced press / hover / none states and automatic calibration. These are component results, separate from the narrative movie.

Current boundary

Touch accuracy against ground truth, frame-to-event latency and live key/MIDI correspondence still require the next measured run. The demo-contract score is not a general legal-accuracy score. SAM is not running inside the glasses.

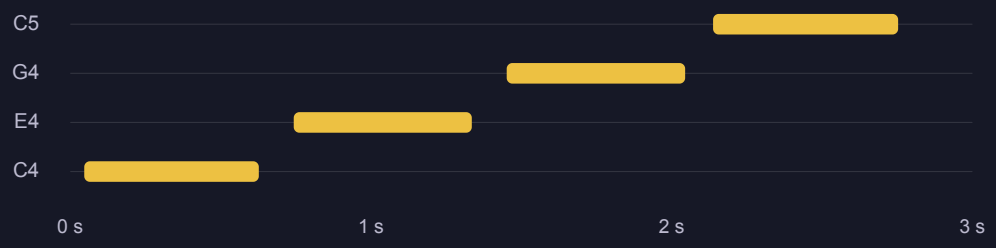

See the film context ↗

Software installed · model loaded

Sol Muse

A physical musical companion

Sol Muse brings the service into a physical object that can speak, move and participate in musical practice. Sol is the robot's name; Muse is its family name.

Actual four-note synthetic fixture output, represented as a piano roll. This is a test melody, not a recorded human lesson.

WHAT WE BUILT

The team prepared project software for a StackChan-based robot and a voice bridge. Music modules cover a moving metronome, a melody notebook that converts a hummed phrase into notes and MIDI, and a rap partner.

HOW IT WORKS

Device firmware connects to a service bridge and musical tools. The notebook pipeline extracts a note sequence and produces notation, editable MIDI and rendered audio. A four-note synthetic fixture is included as a small, inspectable example.

MODELS & TOOLS Muse Responses integration · project-specific model prepared and loaded

LATEST RESULT · 5 NOVEMBER

On 5 November the founder confirmed that the project's own model had been prepared and loaded and its software installed. A successful firmware build and the musical tool modules are present. The notebook fixture produced C4–E4–G4–C5.

EVIDENCE AVAILABLE

Firmware build records, module code and the synthetic notebook outputs are retained. The included MIDI, notation and audio demonstrate the fixture conversion without using a participant's personal recording.

Current boundary

Physical acceptance of each musical mode is tracked separately from installation. This result does not assert that a new foundation model was trained from scratch or that its weights run on the microcontroller. The watch application is a separate, unfinished item.

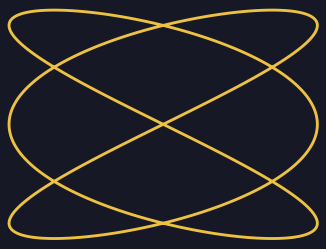

Play fixture audio ↗ Download MIDI ↗ Open ABC notation ↗

Completed campaign · public catalogue

Sound Made Visible

Bi-Level AutoResearch · Sci Sound Labs

A teacher can point to a change in sound when that change has a clear visual counterpart. This research explored mappings between musical quantities and visible form.

24 windows. A frozen evaluator.

59 model requests

11 applied changes to later windows

23 promising calibrations · 1 inconclusive

Illustration of a 3:2 Lissajous relationship. Public numerical results and their limits are linked below.

WHAT WE BUILT

A bounded two-loop research pipeline, a fixed evaluator, renderers, experiment cards and films were developed. The inner loop proposed candidates; the outer loop redirected later work. Both research roles used Muse Wonder in separate contexts.

HOW IT WORKS

Twenty-four windows of 300 seconds produced 59 completed model requests: 48 inner and 11 outer. Eleven outer-loop changes were applied to later windows. The evaluator stayed frozen. The campaign explored ten families and produced nine calibrated families.

MODELS & TOOLS Muse Wonder for both research loops · Muse Wonder Full for the publication and polished media

LATEST RESULT · 5 NOVEMBER

The public Sci Sound Labs section now includes the development history, 24 experiment cards and 18 videos, including a separate 39-second performance loop. The campaign records 23 promising synthetic calibrations and one inconclusive result.

EVIDENCE AVAILABLE

A public English article, experiment catalogue, films and jury report allow direct inspection of the method and numerical results. Early pilots and the stopped first run remain visible as development history.

Current boundary

“Promising” means agreement with a frozen numerical/synthetic model. No physical validation or learning-benefit study was performed. The 24 windows are not 24 discoveries. Arbitrary live-audio recognition and an advantage over a fixed search strategy were not demonstrated.

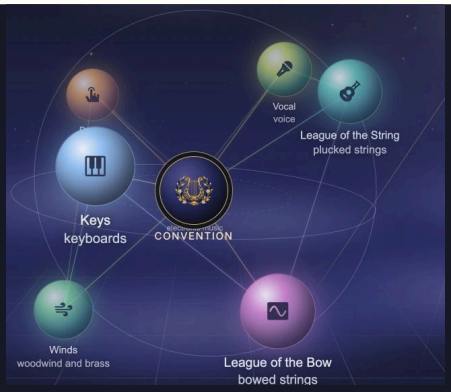

Explore the laboratory ↗ Read the research report ↗

Live entrance · developed identity system

A musical signature & a community

Convention · instrument Leagues · participation

Joining should express a shared commitment: keeping the ability to make music alive. The Convention gives that commitment a form, and a musical signature lets a person see and hear their name.

The instrument-League interface. The page is part of the live portal; the full community program continues to develop.

WHAT WE BUILT

The project developed a name-to-melody engine, staff notation and playback, a Convention, the participant journey, a brand system, seven instrument Leagues and public social pages. The Cookbook connects these pieces into a coherent community design.

HOW IT WORKS

The signature engine maps normalized name characters to notes and renders the result as readable music. The participant journey moves from discovering the community to the Convention, a League, a personal space and an encounter with other musicians.

MODELS & TOOLS A deterministic music-signature engine; Muse supports the wider service experience

LATEST RESULT · 5 NOVEMBER

The current portal's signing flow works, and the public Leagues and personal-space screens open. Facebook and Instagram pages exist. The current visual identity separates the community's golden lyre from the Muse assistant character.

EVIDENCE AVAILABLE

The public Convention and portal can be opened directly. The participant journey, visual system and community roles were developed in the launch Cookbook. Mentor, learner and volunteer express different ways to contribute.

Current boundary

The complete account-linked membership lifecycle and every planned community space are not yet delivered. Multilingual signature edge cases remain. Soul ID, governance, automated social replies and live-stream programs have their own later implementation work.

Visit the Convention ↗ Facebook ↗ Instagram ↗

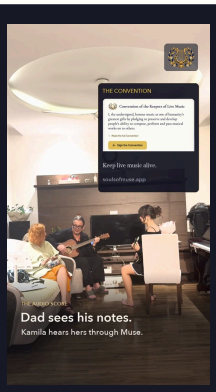

Completed local masters

Music and filmmaking with Muse

Ganesha · the live-action hackathon film

Creative production is a concrete test of collaboration: a story becomes shots, revisions, music and a finished film. The project produced two distinct films.

Frames from the finished films. Full masters are supplied alongside this dossier, with their original production audio.

WHAT WE BUILT

Ganesha developed through screenplay and storyboard work, character references, generated shots, editorial revisions and a composed score. The live-action film follows the loss and return of a piano, a cardboard keyboard, human mentorship and a musician's return to making videos.

HOW IT WORKS

Wonder Full worked on the screenplay and storyboard; Wonder continued direction, review and composition. Muse Image supplied visual references. Krea generated video shots. Local editing and audio rendering assembled the film. Wonder wrote six melodic cells, harmony, percussion patterns and orchestration, preserved as score data and MIDI.

MODELS & TOOLS Muse Wonder Full · Muse Wonder · Muse Image; Krea for generated shots; human direction and local editing

LATEST RESULT · 5 NOVEMBER

Ganesha's completed English-title master runs 82 seconds: 1,968 frames at 24 fps across 13 chapters. The new live-action jury edit runs 2:55.733 and adds the project identity, public pages and short technical explanations.

EVIDENCE AVAILABLE

Both finished films are included in this package. Ganesha's production records preserve completed model outputs, image receipts, score data, MIDI and checksummed masters. The short film is an artistic result with a documented production process.

Current boundary

The live-action story contains staged interactions; it is not end-to-end acceptance evidence for every feature it portrays. Its added narrator uses macOS Daniel, and the studio's question uses macOS Samantha. These voices are not presented as model-generated replies.

Watch Ganesha · 1:22 ↗ Watch the live-action film · 2:56 ↗

FROM THE FIRST SKETCH TO THIS EDITION

The path matters.

The architecture journal, launch Cookbook and project dashboard provided the structure. Current product checks and delivery records supply the result.

Before the event

DEFINE THE HUMAN EXCHANGE

The early architecture journal put the Harness at the centre: shared rules, tools and knowledge around a model, with different device runtimes. The launch Cookbook added the participant journey, the Convention and a coherent visual identity. These are the design baseline.

26 Oct–5 Nov

BUILD THE SERVICE AND ITS TOOLS

The event contribution includes the lesson pilot, speech and approval paths, portal integration, desktop orchestration, studio restoration and interface work. Existing foundations are identified separately from new implementation.

31 October

COMPLETE A BOUNDED RESEARCH CAMPAIGN

The corrected sound-to-form campaign ran 24 five-minute windows. A frozen evaluator, separate research roles, preserved failures and explicit limits turned a collection of visual ideas into an inspectable research result.

3–5 November

CONNECT INTERFACES TO REAL INPUTS

The glasses work gained named service interfaces and a live depth input. Sol Muse received project software and a prepared model. Desktop creative tools supported actual screenplay, reference and review work.

5 November

BRING THE LATEST RESULTS INTO THE RECORD

The current website code is published. Speech output is enabled. The live LiDAR run, installed robot software, current studio interface, Ganesha master and the 2:56 jury film are included in this snapshot.

> **What the early dashboard does not measure**
>
> Workflow states and weighted task percentages are not acceptance tests. This dossier uses concrete delivered outputs and measured runs, with public availability described separately.

SPECIFIC ROLES, VISIBLE OUTPUTS

What the models contributed.

Authorship follows the work produced: a model response, an edit, a score, an experiment or a completed image.

CONTRIBUTOR	CONTRIBUTION IN THIS PROJECT
Muse Wonder	Both roles in the bounded research campaign; desktop reasoning and tool use; Ganesha direction, editorial responses and note-level composition.
Muse Wonder Full	Screenplay and storyboard work through the subscription workflow; research publication, layout and polished media; a recorded restored-studio run.
Muse Spark	Lesson interpretation and review; document and chord-material reading; roles in the three-adviser council.
Muse Image	Character and shot-reference imagery for film production; image generation connected back to the desktop reasoning context.
Other Meta models	Speech recognition and MMS-TTS in the lesson pilot; SAM 3.1 and DINOv2 in local vision work.
People & other tools	The founder set the mission, stories and product direction. Human musicians performed in the live-action film. OpenAI Codex and Claude supported engineering, review and interface work; Kimi supplied the initial sound-visualisation prototype; Krea generated Ganesha shots. Local tools rendered, edited and mixed the films.

> **Iteration produced useful corrections**
>
> The sound pilot was reclassified as feasibility; its note/rest mapping was repaired before the later campaign. Depth calibration corrected the scale difference between RGB and depth coordinates. The film revisions addressed screen direction, continuity and the relationship between picture and score.

The research method and its acceptance were designed and reviewed with OpenAI Codex. Research candidates were data, not executable generated code; the evaluator remained fixed. Use of Meta models is attributed per output rather than inferred from an application name.

A SHORT ROUTE TO INSPECTION

Open the work.

Start with the film, then inspect the service and the research. Each development card points to the material available for that result.

INCLUDED IN THIS PACKAGE

Ganesha · 1:22
Live-action jury film · 2:55.733
Sol's synthetic melody: MIDI, ABC notation and audio.
Standalone web dossier and this PDF.

NEXT VALIDATION STEPS

Full human lesson acceptance and latency; physical acceptance of each robot mode; touch accuracy and live MIDI correspondence; watch integration; multilingual signature edge cases.

> **Evidence snapshot · 5 November 2026 · UTC+7**
>
> Public service, repository, Labs and capability links were checked in this session. Local build, device and production records were reviewed for the latest reported work. Local delivery and public availability are recorded separately. Screens from a narrative film do not replace technical acceptance.

This English edition draws on the architecture journal, the launch Cookbook and the development dashboard, with later delivery records incorporated. Early plans remain design history. Public links may change after this edition.
